

Package ‘Pigengene’

March 31, 2022

Type Package

Title Infers biological signatures from gene expression data

Version 1.20.0

Date 2016-03-31

Author Habil Zare, Amir Foroushani, Rupesh Agrahari, Meghan Short, Isha Mehta, and Neda Emami

Maintainer Habil Zare <zare@u.washington.edu>

biocViews GeneExpression, RNASeq, NetworkInference, Network, GraphAndNetwork, BiomedicalInformatics, SystemsBiology, Transcriptomics, Classification, Clustering, DecisionTree, DimensionReduction, PrincipalComponent, Microarray, Normalization, ImmunoOncology

Depends R (>= 4.0.3), graph, BiocStyle (>= 2.18.1)

Description Pigengene package provides an efficient way to infer biological signatures from gene expression profiles. The signatures are independent from the underlying platform, e.g., the input can be microarray or RNA Seq data. It can even infer the signatures using data from one platform, and evaluate them on the other. Pigengene identifies the modules (clusters) of highly coexpressed genes using coexpression network analysis, summarizes the biological information of each module in an eigengene, learns a Bayesian network that models the probabilistic dependencies between modules, and builds a decision tree based on the expression of eigengenes.

License GPL (>=2)

|-------------------|--|
| Pigengene-package | <i>Infers robust biological signatures from gene expression data</i> |
|-------------------|--|

Description

Pigengene identifies gene modules (clusters), computes an eigengene for each module, and uses these biological signatures as features for classification. The resulting biological signatures are very robust with respect to the profiling platform. For instance, if Pigengene computes a biological signature using a microarray dataset, it can infer the same signature in an RNA Seq dataset such that it is directly comparable across the two datasets.

Details

| | |
|----------|------------|
| Package: | Pigengene |
| Type: | Package |
| Version: | 0.99.0 |
| Date: | 2016-04-25 |
| License: | GPL (>= 2) |

The main function is [one.step.pigengene](#) which requires a gene expression profile and the corresponding conditions (types). Individual functions are provided to facilitate running the pipeline in a customized way. Also, the inferred biological signatures (computed eigengenes) are useful for other supervised or unsupervised analyses.

In most functions of this package, eigenegenes are computed or used as robust biological signatures. Briefly, each eigengene is a weighted average of the expression of all genes in a module (cluster), where the weights are adjusted in a way that the explained variance is maximized.

```

```

data(mds)
d1 <- rbind(aml,mds)
Labels <- c(rep("AML",nrow(aml)),rep("MDS",nrow(mds)))
names(Labels) <- rownames(d1)
p1 <- one.step.pigengene(Data=d1,saveDir='pigengene', bnNum=10, verbose=1,
  seed=1, Labels=Labels, toCompact=FALSE, doHeat=FALSE)
plot(p1$c5treeRes$c5Trees[["34"]])
## See pigengene for results.

```

aml

AML gene expression profile

Description

Gene expression profile of 202 acute myeloid leukemia (AML) cases from Mills et al. study. The profile was compared with the profile of 164 myelodysplastic syndromes (MDS) cases and only the 1000 most differentially expressed genes are included.

Usage

```
data("aml")
```

Format

A numeric matrix

Details

The columns and rows are named according to the genes Entrez, and patient IDs, respectively. The original data was produced using Affymetrix Human Genome U133 Plus 2.0 Microarray. Mills et al. study is part of the MILE Study (Microarray Innovations In LEukemia) program, and aimed at prediction of AML transformation in MDS.

Value

It is a 202*1000 numeric matrix.

```

| | |
|---------|---------------------------------------|
| balance | <i>Balances the number of samples</i> |
|---------|---------------------------------------|

Description

Oversamples data by repeating rows such that each condition has roughly the same number of samples.

Usage

```
balance(Data, Labels, amplification = 5, verbose = 0, naTolerance=0.05)
```

Arguments

| | |
|---------------|---|
| Data | A matrix or data frame containing the expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| Labels | A (preferably named) vector containing the Labels (condition types) for Data. Names must agree with rows of Data. |
| amplification | An integer that controls the number of repeats for each condition. The number of all samples roughly will be multiplied by this factor after oversampling. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| naTolerance | Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input . |

Value

| | |
|----------------|--|
| A list of: | |
| balanced | The matrix of oversampled data |
| Reptimes | A vector of integers named by conditions reporting the number of repeats for each condition. |
| origSampleInds | The indices of rows in balanced that correspond to the original samples before oversampling |

Examples

```
data(aml)
data(mds)
d1 <- rbind(aml,mds)
Labels <- c(rep("AML",nrow(aml)),rep("MDS",nrow(mds)))
names(Labels) <- rownames(d1)
b1 <- balance(Data=d1, Labels=Labels)
d2 <- b1$balanced
```

| | |
|----------------|---|
| calculate.beta | <i>Estimates an appropriate power value</i> |
|----------------|---|

Description

The [WGCNA](#) package assumes that in the coexpression network the genes are connected with a power-law distribution. Therefore, it need a soft-thresholding power for network construction, which is estimated by this auxiliary function.

Usage

```
calculate.beta(saveFile = NULL, RsquaredCut = 0.8, Data, doThreads=FALSE,
  verbose = 0)
```

Arguments

| | |
|-------------|---|
| saveFile | The file to save the results in. Set to NULL to disable. |
| RsquaredCut | A threshold in the range [0,1] used to estimate the power. A higher value can increase power. For technical use only. See pickSoftThreshold for more details. |
| Data | A matrix or data frame containing the expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| doThreads | Boolean. Allows WGCNA to run a little faster using multi-threading but might not work on all systems. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |

Value

A list of:

| | |
|-------------|---|
| sft | The full output of pickSoftThreshold function |
| power | The estimated power (beta) value |
| powers | The numeric vector of all tried powers |
| RsquaredCut | The value of input argument RsquaredCut |

| | |
|-----------|---------------------------------------|
| check.nas | <i>Removes NAs from a data matrix</i> |
|-----------|---------------------------------------|

Description

Checks Data for NA values.

Usage

```
check.nas(Data, naTolerance=0.05, na.rm=TRUE)
```

Arguments

| | |
|-------------|---|
| Data | A matrix or data frame containing the expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| naTolerance | A number in the 0-1 range. If the frequency of NAs in a column of Data is more than this threshold, then that column will be removed. |
| na.rm | If TRUE, NAs in the Data will be replaced with the average of the column, however, if the frequency of NAs in the column is too high (i.e., more than naTolerance), the whole column will be removed. |

Value

A list of:

| | |
|---------------|---|
| cleaned | The cleaned data with no NA value. Rows are the same as Data, but some columns may be deleted. |
| tooNaGenes | A character vector of those genes (i.e., column names of Data) that had too many NAs, and therefore were removed. |
| replacedNaNum | The number of NA entries in the matrix that were replaced with the average of the corresponding column (gene). |

dim(c1$cleaned)
c1$tooNaGenes
rm(aml)
```

check.pigengene.input *Quality check on the input*

Description

Checks Data and Labels for NA values, row and column names, etc.

Usage

```
check.pigengene.input(Data, Labels, na.rm = FALSE, naTolerance=0.05)
```

Arguments

| | |
|--------|---|
| Data | A matrix or data frame containing the expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| Labels | A (preferably named) vector containing the Labels (condition types) for Data. Names must agree with rows of Data. |

| | |
|-------------|---|
| na.rm | If TRUE, NAs in the Data will be replaced with the average of the column, however, if the frequency of NAs in the column is too high, the whole column will be removed. |
| naTolerance | Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input . |

Value

A list of:

| | |
|--------|---|
| Data | The checked Data matrix, NA possibly removed and rows are ordered as names of Labels. |
| Labels | The checked vector of Labels |

Author(s)

Habil Zare

Examples

```
data(aml)
Labels <- c(rep("AML", nrow(aml)))
names(Labels) <- rownames(aml)
c1 <- check.pigengene.input(Data=aml, Labels=Labels, na.rm=TRUE)
Data <- c1$Data
Labels <- c1$Labels
```

combine.networks

Combines two or more networks

Description

Takes as input two or more adjacency matrices, and the corresponding contributions. Computes a combined network (weighted graph) in which the weight on an edge between two nodes is an average of the weights on the same edge in the input networks.

Usage

```
combine.networks(nets, contributions, outPath, midfix="",
  powerVector=1:20, verbose=1, RsquaredCut=0.75, minModuleSize=5,
  doRemoveTOM=TRUE, datExpr, doReturnNetworks=FALSE, doSave=FALSE, doIdentifyModule=TRUE)
```

Arguments

| | |
|------------------|---|
| nets | A list of adjacency matrices (networks), which can be generated using e.g., the <code>WGCNA::adjacency</code> function. Rows and columns must be named. |
| contributions | A numeric vector with the same length as nets. In computing the average weight on each edge in the combined network, first the edge weights from individual networks are multiplied by their corresponding contributions, then the result will be divided by the sum of weights of all networks containing this edge. |
| outPath | A string to the path where plots and results will be saved. |
| midfix | An optional string used in the output file names. |
| powerVector | A numeric vector of power values that are tried to find the best one. See <code>WGCNA::pickSoftThreshold</code> documentation. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| RsquaredCut | A threshold in the range [0,1] used to estimate the power. A higher value can increase power. For technical use only. See <code>pickSoftThreshold</code> for more details. |
| minModuleSize | The value that controls the minimum number of genes per module. |
| doRemoveTOM | A boolean determining the big TOM file must remove or not. |
| datExpr | The expression matrix that <code>WGCNA::blockwiseModules</code> uses for fine-tuning and removing genes from modules. This is not an ideal behavior by <code>WGCNA</code> . |
| doReturnNetworks | A boolean value to determine whether to return Network, which is relatively a big matrix (typically GBs). Set to FALSE not to waste memory. |
| doSave | A boolean value to determine whether the whole output of this function (typically 1-2 GBs) should be saved as combinedNetwork. Set to FALSE not to waste disk space. |
| doIdentifyModule | A boolean value to determine whether modules should be identified. Set it to FALSE if you just need the network, not the modules. |

Value

| | |
|----------------------------------|--|
| A list with following components | |
| call | The command that created the results |
| midfix | The input argument |
| Network | The adjacency matrix of the combined network |
| denominators | A matrix, each cell of which is the sum of weights of all networks contributing to the edge corresponding to that cell |
| power | The power (beta) value used for the combined network |
| fits | The fit indices calculated for the combined network |
| net | The output of <code>WGCNA::blockwiseModules</code> containing the module information in its colors field |
| modules | The output of <code>WGCNA::blockwiseModules</code> |
| combinedNetworkFile | The path to the saved file containing combinedNetwork |

Note

If the networks have different node sets, the combined network will be computed on the union of nodes.

See Also

WGCNA::blockwiseModules, WGCNA::TOMsimilarity, and WGCNA::pickSoftThreshold.fromSimilarity

Examples

```
data(aml)
data(mds)
nets <- list()
## Make the coexpression networks:
nets[["aml"]] <- abs(stats::cor(aml[,1:200]))
nets[["mds"]] <- abs(stats::cor(mds[,1:200]))
## Combine them:
combined <- combine.networks(nets=nets, contributions=c(nrow(aml), nrow(mds)),
                             outputPath=".", datExpr=rbind(aml, mds)[,1:200])
print(table(combined$modules))
```

compact.tree

Reduces the number of genes in a decision tree

Description

In a greedy way, this function removes the genes with smaller weight one-by-one, while assessing the accuracy of the predictions of the resulting trees.

Usage

```
compact.tree(c5Tree, pigengene, Data=pigengene$Data, Labels=pigengene$Labels,
             testD=NULL, testL=NULL, saveDir=".", verbose=0)
```

Arguments

| | |
|-----------|---|
| c5Tree | A decision tree of class C50 that uses module eigengenes, or NULL. If NULL, If NULL, expression plots for all modules are created. |
| pigengene | A object of pigengene-class , output of compute.pigengene |
| Data | A matrix or data frame containing the expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| Labels | Labels (condition types) for the (training) expression data. It is a named vector of characters. Data will be subset according to these names. |
| testD | The test expression data, for example, from an independent dataset. Optional. |
| testL | Labels (condition types) for the (test) expression data. Optional. |

| | |
|---------|---|
| saveDir | Where to save the plots of the tree(s) |
| verbose | Integer level of verbosity. 0 means silent and higher values produce more details of computation. |

Value

A list with following elements is invisibly returned:

| | |
|------------------|--|
| call | The call that created the results |
| predTrain | Prediction using projected data without compacting |
| predTrainCompact | Prediction after compacting |
| genes | A character vector of all genes in the full tree before compacting |
| genesCompacted | A character vector of all genes in the compacted tree |
| trainErrors | A matrix reporting errors on the train data. The rows are named according to the number of removed genes. Each column reports the number of misclassified samples in one condition (type) except the last column that reports the total. |
| testErrors | A matrix reporting errors on the test data similar to trainErrors |
| queue | A numeric vector named by all genes contributing to the full tree before compacting. The numeric values are weights increasingly ordered by absolute value. |
| pos | The number of removed genes |
| txtFile | Confusion matrices and other details on compacting are reported in this text file |

Examples

```
## Data:
data(aml)
data(mds)
data(pigengene)
d1 <- rbind(aml,mds)

## Fiting the trees:
trees <- make.decision.tree(pigengene=pigengene, Data=d1,
saveDir="trees", minPerLeaf=14:15, doHeat=FALSE,verbose=3,
toCompact=FALSE)
```

```
c1 <- compact.tree(c5Tree=trees$c5Trees[["15"]], pigengene=pigengene,
  saveDir="compacted", verbose=1)
```

| | |
|-------------------|--------------------------------|
| compute.pigengene | <i>Computes the eigengenes</i> |
|-------------------|--------------------------------|

Description

This function takes as input the expression data and module assignments, and computes an eigengene for each module using PCA.

Usage

```
compute.pigengene(Data, Labels, modules, saveFile = "pigengene.RData",
  selectedModules = "All", amplification = 5, doPlot = TRUE,
  verbose = 0, dOrderByW = TRUE, naTolerance=0.05)
```

Arguments

| | |
|-----------------|---|
| Data | A matrix or data frame containing the training expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| Labels | A (preferably named) vector containing the Labels (condition types) for the training Data. Names must agree with rows of Data. |
| modules | A numeric vector, named by genes, that reports the module (clustering) assignments. |
| saveFile | The file to save the results. NULL will disable saving, and thus requires doPlot to be FALSE. |
| selectedModules | A numeric vector determining which modules to use, or set to "All" (default) to include every module. |
| amplification | An integer that controls the number of repeats for each condition. The number of all samples roughly will be multiplied by this factor after oversampling. See balance . |
| doPlot | Boolean determining whether heatmaps of expression of eigengenes should be plotted and saved. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| dOrderByW | If TRUE, the genes will be ordered in the csv file based on their absolute weight in the corresponding module. |
| naTolerance | Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input . |

Details

Rows of Data are oversampled using [balance](#) so that each condition has roughly the same number of samples. [moduleEigengenes](#) computes an eigengene for each module using PCA.

Value

An object of [pigengene-class](#).

dcor.matrix

Computes distance correlation for give matrix

Description

This function computes the distance correlation between every pair of columns of the input data matrix.

Usage

```
dcor.matrix(Data)
```

Arguments

Data A matrix containing the data

Details

Using for loops, all pairs of columns are passed to `link[energy]{dcor}` function from `link[energy]{energy-package}`.

Value

A numeric square matrix. The number of rows and columns is equal to the number of columns of Data and they are named accordingly.

Note

This function uses for loops, which are not efficient for an input matrix with too many columns.

```
## Data:
data(aml)
dcor1 <- dcor.matrix(Data=aml[,1:5])
dcor1

## Comparison with Pearson:
cor1 <- abs(cor(aml[,1:5]))
## With 202 samples, distance and Pearson correlations do not differ much:
dcor1-cor1
dcor2 <- dcor.matrix(Data=aml[1:20,1:5])
cor2 <- abs(cor(aml[1:20,1:5]))
## Distance correlation is more robust if fewer samples are available:
```

```
dcor2-cor2
plot(dcor2-cor1,cor1-cor2,xlim=c(-0.5,0.5),ylim=c(-0.5,0.5))
```

draw.bn

Draws a Bayesian network

Description

Draws the BN using appropriate colors and font size.

Usage

```
draw.bn(BN, plotFile = NULL, inputType = "ENTREZIDat", edgeColor = "blue",
  DiseaseCol = "darkgreen", DiseaseFill = "red", DiseaseChildFill = "pink",
  nodeCol = "darkgreen", nodeFill = "yellow", moduleNamesFile = NULL,
  mainText = NULL, nodeFontSize = 14 * 1.1, verbose = 0)
```

Arguments

| | |
|------------------|--|
| BN | An object of bn-class |
| plotFile | If not NULL, the plot will be saved here. |
| inputType | The type of gene IDs in BN |
| edgeColor | The color of edges |
| DiseaseCol | The color of the border of the Disease node |
| DiseaseFill | The color of the area inside the Disease node |
| DiseaseChildFill | The color of the area inside the children of the Disease node |
| nodeCol | The color of the border of the usual nodes excluding Disease and its children |
| nodeFill | The color of the area inside the usual nodes |
| moduleNamesFile | An optional csv file including the information to rename the nodes name. See <code>codereaname.node</code> . |
| mainText | The main text shown at the top of the plot |
| nodeFontSize | Adjusts the size of nodes |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |

Value

A list with following components:

| | |
|-----------|---|
| call | The call that created the results |
| BN | An echo of input BN argument |
| renamedBN | An object of bn-class when <code>moduleNamesFile</code> is provided |
| gr | The full output of graphviz.plot function |

```

eigengenes33

Eigengenes of 33 modules

Description

This list contains partial eigengenes computed from AML and MDS gene expression profiles provided by Mills et al. These data are included to illustrate how to use [Pigengene-package](#) and also to facilitate reproducing the results presented in the corresponding paper.

Usage

```
data(eigengenes33)
```

Format

A list

Details

The top 9166 differentially expressed genes were identified and their expressions in AML were used for identifying 33 modules. The first column, ME0, corresponds to module 0 (outliers) and is usually ignored. The eigengene for each module was obtained using [compute.pigengene](#) function. Oversampling was performed with `amplification=5` to adjust for unbalanced sample-size.

Value

It is a list of 3 objects:

`aml` A 202 by 34 matrix. Each column reports the values of a module eigengene for AML cases.

`mds` A 164 by 34 matrix for MDS cases with columns similar to `aml`.

`modules` A numeric vector of length 9166 labeling members of each module. Named by Entrez ID.

gene.mapping

Maps gene IDs

Description

Takse as input gene IDs in a convention, say REFSEQ, and converts them to another convention.

Usage

```
gene.mapping(ids, inputType = "REFSEQ", outputType = "SYMBOL",
  leaveNA = TRUE, inputDb = "Human", outputDb = inputDb,
  verbose = 0)
```

Arguments

| | |
|------------|--|
| ids | A character vector of input gene IDs |
| inputType | The type of input IDs. |
| outputType | The type of output IDs. If it is a character vector, mapping will be done for each element. |
| leaveNA | If TRUE, the IDs that were not matched are left with NAs in the second column of the output, otherwise the input IDs are returned. |
| inputDb | The input data base. Use org.Hs.eg.db for human and org.Mm.eg.db for mouse. The default "Human" character uses the former. |
| outputDb | The output data base. If it is a list, mapping will be done for each element. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |

Details

It can map homologous genes between species e.g. from mouse to human. If more than 1 ID found for an input gene, only one of them is returned.

Value

A matrix of characters with 3 columns: input, output1, and output2. The last one is guaranteed not to be NA.

print(g1)

## Mapping to multiple convention
library(org.Mm.eg.db)
g2 <- gene.mapping(ids=c("NM_170730", "NM_001013580"),
  inputType="REFSEQ", inputDb=org.Mm.eg.db,
  outputType=c("SYMBOL", "ENTREZID"),
  outputDb=list(org.Hs.eg.db, org.Mm.eg.db), verbose=1)
print(g2)
```

get.enriched.pw

Performs pathway over representation analysis

Description

Takes as input a vector or list of gene IDs in any convention, and performs over representation analysis.

Usage

```
get.enriched.pw(genes, idType, pathwayDb, ont=c("BP", "MF", "CC"),
  Org="Human", OrgDb=NULL, outPath, pvalueCutoff=0.05,
  pAdjustMethod="BH", fontSize=14, verbose=0)
```

Arguments

| | |
|---------------|---|
| genes | A character vector or a named list of genes for which pathway over representation analysis to be done. |
| idType | A string describing the type of input gene ID e.g., "ENTREZID", "REFSEQ", "SYMBOL". |
| pathwayDb | A character vector determining which enrichment database to be used e.g., "GO", "KEGG", "REACTOME", or "NCG". |
| ont | GO ontology terms to be analysed e.g., "BP", "MF" or "CC". Default is all three. |
| Org | A character string equal to "Human" or "Mouse" determining the reference organism to be used. For "Human" and "Mouse" org.Hg.eg.db and org.Mm.eg.db will be used, respectively. If Org is not NULL, OrgDb must be NULL. |
| OrgDb | The reference data base to be used. Use e.g. org.Ce.eg.db for 'Celegans' when analysing Celegans data. If OrgDb is not NULL, Org must be NULL. |
| outPath | A file path where results will be saved. |
| pvalueCutoff | A numerical value that determines a cutoff of adjusted pValue. |
| pAdjustMethod | A string passed to the clusterProfiler:: enrichGO function to determine the method for adjusting the p-value. Options include "holm", "hochberg", "hommel", "bonferroni", "BH", "BY", "fdr", "none". |
| fontSize | A numerical value that determines the font size of the y-axis and the title in the plot. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |

Value

A list:

| | |
|---------------|--|
| EnrichResults | A list of output of enrichment analysis for different database analyzed. |
| noEnrichment | A vector of database names in which no enriched pathways were found. |

The output is saved for each selected module under the "moduleName_enrichment" folder. There is a subfolder that includes an excel file and plot(s). Each sheet in the excel file corresponds to a pathway database (KEGG in the below example). Each row is an overrepresented pathway.

```

| | |
|-----------------|---|
| get.fitted.leaf | <i>Returns the leaf for each sample</i> |
|-----------------|---|

Description

Taking as input a tree and data, this function determines the leaf each sample will fall in.

Usage

```
get.fitted.leaf(c5Tree, inpDTemp, epsi = 10-7)
```

Arguments

| | |
|----------|---|
| c5Tree | A decision tree of class C50 that uses module eigengenes, or NULL. If NULL, expression plots for all modules are created. |
| inpDTemp | The possibly new data matrix with samples on rows |
| epsi | A small perturbation to resolve the boundary issue |

Value

A numeric vector of node indices named by samples (rows of inpDTemp)

Note

This function is tricky because C50 uses a global variable.

f1 <- get.fitted.leaf(c5Tree=trees$c5Trees[["15"]],
inpDTemp=pigengene$eigengenes)
```

get.genes

List the (most relevant) genes for a decision tree.

Description

This function returns all genes that are left after shrinking (compacting) a given tree. If enhance is set to TRUE, it makes sure that the output contains at least two genes from each used module.

Usage

```
get.genes(c5Tree = NULL, pigengene = NULL, queue = NULL, modules = NULL, pos=0,
enhance = TRUE)
```

Arguments

| | |
|-----------|--|
| queue | A character vector. The membership queue for a decsision tree. |
| pos | Number of genes that are considered from removal. Same interpretation as in preds.at |
| enhance | If enhance is set to TRUE, the function makes sure that the output contains at least two genes from each used module. Otherwise, exactly the pos first elements of the queue are removed from consideration. |
| modules | Named character vector listing the module assignments. |
| c5Tree | A decision tree of class C50. |
| pigengene | An object in pigengene-class , usually created by compute.pigengene . |

Details

This function needs modules and queue, or alternatively, c5Tree and pigengene.

Value

A character vector containing the names of the genes involved in the modules whose eigengenes are used in the tree. If $pos > 0$, the first pos such genes with lowest absolute membership in their respective modules are filtered.

## Data:
data(aml)
data(mds)
data(pigengene)
d1 <- rbind(aml,mds)

## Fiting the trees:
trees <- make.decision.tree(pigengene=pigengene, Data=d1,
saveDir="trees", minPerLeaf=15, doHeat=FALSE,verbose=3,
toCompact=FALSE)
g1 <- get.genes(c5Tree=trees$c5Trees[["15"]],pigengene=pigengene)
```

| | |
|-------------------|---|
| get.used.features | <i>Return the features used in a tree</i> |
|-------------------|---|

Description

Only some of the features will be automatically selected and used in a decision tree. However, an object of class C5.0 does not have the selected feature names explicitly. This function parses the tree component and extracts the names of features contributing to the tree.

Usage

```
get.used.features(c5Tree)
```

Arguments

| | |
|--------|-----------------------------|
| c5Tree | A decision tree of class 50 |
|--------|-----------------------------|

Value

A character vector of the names of features (module eigengenes) contributing to the input decision tree.

Author(s)

Amir Foroushani

```

learn.bn

Learns a Bayesian network

Description

This function takes as input the eigengenes of all modules and learns a Bayesian network using bnlearn package. It builds several individual networks from random staring networks by optimizing their score. Then, it infers a consensus network from the ones with relatively "higher" scores. The default hyper-parameters and arguments should be fine for most applications.

Usage

```
learn.bn(pigengene=NULL, Data=NULL, Labels=NULL, bnPath = "bn", bnNum = 100,
  consensusRatio = 1/3, consensusThresh = "Auto", doME0 = FALSE,
  selectedFeatures = NULL, trainingCases = "All", algo = "hc", scoring = "bde",
  restart = 0, pertFrac = 0.1, doShuffle = TRUE, use.Hartemink = TRUE,
  bnStartFile = "None", use.Disease = TRUE, use.Effect = FALSE, dummies = NULL,
  tasks = "All", onCluster = !(which.cluster()$cluster == "local"),
  inds = 1:ceiling(bnNum/perJob), perJob = 2, maxSeconds = 5 * 60,
  timeJob = "00:10:00", bnCalculationJob = NULL, seed = NULL, verbose = 0,
  naTolerance=0.05)
```

Arguments

| | |
|-----------|---|
| pigengene | An object from pigengene-class . The output of compute.pigengene function. |
| Data | A matrix or data frame containing the training data with eigengenes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| Labels | A (preferably named) vector containing the Labels (condition types) for the training data. Names must agree with rows of Data. |
| bnPath | The path to save the results |

| | |
|------------------|---|
| bnNum | The total number of individual networks. In practice, the number of learnt networks can be less than bnNum because some jobs may take too long and be terminated. |
| consensusRatio | A numeric in the range 0-1 that determines what portion of highly scored networks should be used to build the consensus network |
| consensusThresh | A vector of thresholds in the range 0-1. For each threshold <i>t</i> , a consensus network will be build by considering the arcs that are present in at least a fraction of <i>t</i> of the individual networks. Alternatively, if it is "Auto" (the default), the threshold will be automatically set to the mean plus the standard deviation of the frequencies (strengths) of all arcs in the individual networks. |
| doME0 | If TRUE, module 0 (the outliers) will be considered in learning the Bayesian network. |
| selectedFeatures | A character vector. If not NULL, only these features (eigengenes) will be used. |
| trainingCases | A character vector that determines which cases (samples) should be considered for learning the network. |
| algo | The algorithm that bnlearn uses for optimizing the score. The default is "hc" (hill climbing). See arc.strength for other options and more details. |
| scoring | A character determining the scoring criteria. Use 'bde' and 'bic' for the Bayesian Dirichlet equivalent and Bayesian Information Criterion scores, respectively. See score for technical details. |
| restart | The number of random restarts. For technical use only. See hc . |
| pertFrac | A numeric in the range 0-1 that determines the number of attempts to randomly insert/remove/reverse an arc on every random restart. For technical use only. |
| doShuffle | The ordering of the features (eigengenes) is important in making the initial network. If doShuffle=TRUE, they will be shuffled before making every initial network. |
| use.Hartemink | If TRUE, Hartemink algorithm will be used to discretize data. Otherwise, interval discretization will be applied. See bnlearn: discretize . |
| bnStartFile | Optionally, learning can start from a Bayesian network instead of a random network. bnStartFile should contain a list called selected and selected\$BN should be an object of bn-class . Non-technical users can set to "None" to disable. |
| use.Disease | If TRUE, the condition variable Disease will be included in the network, which cannot be the child of any other variable. |
| use.Effect | If TRUE, the condition variable beAML will be included in the network, which cannot be the parent of any other variable. |
| dummies | A vector of numeric values in the range 0-1. Dummy random variables will be added to the Bayesian network to check whether the learning process is effective. For development purposes only. |
| tasks | A character vector and a subset of c("learn", "harvest", "consensus", "graph") that identifies the tasks to be done. Useful if part of the analysis was done previously, otherwise set to "All". |

| | |
|------------------|---|
| onCluster | A Boolean variable that is FALSE if the learning is not done on a computer cluster. |
| inds | The indices of the jobs that are included in the analysis. |
| perJob | The number of individual networks that are learnt by 1 job. |
| maxSeconds | An integer limiting computation time for each training job that runs locally, i.e., when oncluster=FALSE. |
| timeJob | The time in "hh:mm:ss" format requested for each job if they are running on a computer cluster. |
| bnCalculationJob | A script used to submit jobs to the cluster. Set to NULL if not using a cluster. |
| seed | The random seed that can be set to an integer to reproduce the same results. |
| verbose | Integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| naTolerance | Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input . |

Details

For learning a Bayesian network with tens of nodes (eigengenes), bnNum=1000 or higher is recommended. Increasing consensusThresh generally results in a network with fewer arcs. Nagarajan et al. proposed a fundamental approach that determines this hyper-parameter based on the background noise. They use non-parametric bootstrapping, which is not implemented in the current package yet. The default values for the rest of the hyper-parameters should be fine for most applications.

Value

A list of:

| | |
|--------------------|---|
| consensusThresh | The vector of thresholds as described in the arguments. |
| indvPath | The path where the individual networks were saved. |
| moduleFile | The file containing data in appropriate format for bnlearn package and the black-list arcs. |
| scoreFile | The file containing the record of the successively jobs and the scores of the corresponding individual networks. |
| consensusFile | The file containing the consensus network and its BDe and BIC scores. |
| bnModuleRes | The result of bn.module function. Useful mostly for development. |
| runs | A list containing the record of successful jobs. |
| scores | The list saved in scoreFile. |
| consensusThreshRes | The full output of consensus.thresh() function. |
| consensus1 | The consensus Bayesian network corresponding to the first threshold. It is the output of consensus function and consensus1\$BN is an object of bn-class . |

| | |
|---|---|
| scorePlot | The output of <code>plot.scores</code> functions, containing the scores of individual networks. |
| graphs | The output of <code>plot.graphS</code> function, containing the BDe score of the consensus network. |
| timeTaken | An object of <code>difftime</code> -class recording the learning wall-time. |
| <code>use.Disease</code> , <code>use.Effect</code> , <code>use.Hartemink</code> | Some of the input arguments. |

Note

Running the jobs on a cluster needs `bnCalculationJob` script, which is NOT included in the package yet.

| | |
|--------------------|--|
| make.decision.tree | <i>Creates a decision tree to classify samples using the eigengenes values</i> |
|--------------------|--|

Description

A decision tree in [Pigengene-package](#) uses module eigengenes to build a classifier that distinguishes the different classes. Briefly, each eigengene is a weighted average of the expression of all genes in the module, where the weight of each gene corresponds to its membership in the module.

Usage

```

make.decision.tree(pigengene, Data,
  Labels = structure(pigengene$annotation[rownames(pigengene$eigengenes),
    1], names = rownames(pigengene$eigengenes)),
  testD = NULL, testL = NULL, selectedFeatures = NULL,
  saveDir = "C5Trees", minPerLeaf = NULL, useMod0 = FALSE,
  costRatio = 1, toCompact = NULL, noise = 0, noiseRepNum = 10, doHeat=TRUE,
  verbose = 0, naTolerance=0.05)

```

Arguments

| | |
|------------------|--|
| pigengene | The pigengene object that is used to build the decision tree. See pigengene-class . |
| Data | The training expression data |
| Labels | Labels (condition types) for the (training) expression data. It is a named vector of characters. Data and pigengene will be subset according to these names. |
| testD | The test expression data, for example, from an independent dataset. Optional. |
| testL | Labels (condition types) for the (test) expression data. Optional. |
| selectedFeatures | A numeric vector determining the subset of eigengenes that should be used as potential predictors. By default ("All"), eigengenes for all modules are considered. See also useMod0. |
| saveDir | Where to save the plots of the tree(s). |
| minPerLeaf | Vector of integers. For each value, a tree will be built requiring at least that many nodes on each leaf. By default (NULL), several trees are built, one for each possible value between 2 and 10 percent of the number of samples. |

| | |
|--------------------|--|
| useMod0 | Boolean. Whether to allow the tree(s) to use the eigengene of module 0, which corresponds to the set of outlier, as a proper predictor. |
| costRatio | A numeric value effective only for 2 groups classification. The default value (1) considers the misclassification of both conditions as equally disadvantageous. Change this value to a larger or smaller value if you are more interested in the specificity of predictions for condition 1 or condition 2, respectively. |
| toCompact | An integer. The tree with this minPerLeaf value will be compacted (shrunk). Compacting in this context means reducing the number of required genes for the calculation of the relevant eigengenes and making the predictions using the tree. If NULL (default), the (presumably) most general proper tree (corresponding to the largest value in the minPerLeaf vector for which a tree could be constructed) is compacted. Set to FALSE to turn off compacting. |
| noise, noiseRepNum | For development purposes only. These parameters allow investigating the effect of gaussian noise in the expression data on the accuracy of the tree for test data. |
| doHeat | Boolean. Set to FALSE not to plot the heatmaps for faster computation. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| naTolerance | Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input . |

Details

This function passes the input eigengenes and appropriate arguments [C5.0](#) function from C50 package.

Value

A list with following elements:

| | |
|-------------|---|
| call | The call that created the results |
| c5Trees | A list, with one element of class C5.0 for each attempted minNodesperleaf value. The list is named with the corresponding values as characters. |
| minPerLeaf | A numeric vector enumerating all of the attempted minPerLeaf values. |
| compacted | The full output of compact.tree function if toCompact is not FALSE |
| heat | The output of module.heatmap function for the full tree if doHeat is not FALSE |
| heatCompact | The output of module.heatmap function for the compacted tree if toCompact is not FALSE |
| noisy | The full output of noise.analysis function if noise is not 0. For development and evaluation purposes only. |
| leafLocs | A matrix reporting the leaf for each sample on 1 row. The columns are named according to the corresponding minNodesperleaf value. |
| toCompact | Echos the toCompact input argument |
| costs | The cost matrix |
| saveDir | The directory where plots are saved in |

Note

For faster computation in an initial, explanatory run, turn off compacting, which can take a few minutes, with `toCompact=FALSE`.

  saveDir="trees", minPerLeaf=14:15, doHeat=FALSE,verbose=3,
  toCompact=15)
```

mds

MDS gene expression profile

Description

Gene expression profile of 164 myelodysplastic syndromes (MDS) cases from Mills et al. study. The profile was compared with the profile of 202 acute myeloid leukemia (AML) cases and only the 1000 most differentially expressed genes are included.

Usage

```
data("mds")
```

Format

A numeric matrix

Details

The columns and rows are named according to the genes Entrez, and patient IDs, respectively. The original data was produced using Affymetrix Human Genome U133 Plus 2.0 Microarray. Mills et al. study is part of the MILE Study (Microarray Innovations In LEukemia) program, and aimed at prediction of AML transformation in MDS.

Value

It is a 164*1000 numeric matrix.

Note

This profile includes data of the 25 chronic myelomonocytic leukemia (CMLL) cases that can have different expression signatures according to Mills et al.

message.if

Conditional messaging.

Description

Messages only if verbose is more than 0 and write in a text file if provided.

Usage

```
message.if(me=NULL, verbose=0, txtFile=NULL, append=TRUE, ...)
```

Arguments

| | |
|---------|---|
| me | The Message. Can be a character vector. |
| verbose | A integer. |
| txtFile | The text file in which the message will be written. Set to NULL to disable. |
| append | logical. Set to FALSE to overwrite txtFile. |
| ... | Arguments to be passed to capture.output. |

Value

NULL

Examples

```
message.if("Hello world!", verbose=1)
```

| | |
|----------------|-----------------------------------|
| module.heatmap | <i>Plots heatmaps for modules</i> |
|----------------|-----------------------------------|

Description

This function takes as input a tree and an object from [pigengene-class](#) and per any module used in the tree, it plots one gene expression heatmap. Alternatively, it can plot a heatmap for every module in the given pigengene object.

Usage

```
module.heatmap(c5Tree=NULL, pigengene, mes=NULL, saveDir, testD = NULL,
  testL = NULL, pos = 0, verbose=0, doAddEigengene=TRUE, scalePngs=1, ...)
```

Arguments

| | |
|----------------|---|
| c5Tree | A decision tree of class C50 that uses module eigengenes, or NULL. If NULL, expression plots for all modules are created. |
| pigengene | A object of pigengene-class , output of compute.pigengene |
| mes | A character vector that determines which modules to plot, e.g., c("ME3","ME5"). Set it to NULL to plot a heatmap for every module. This argument will be ignored if c5Tree is not NULL. |
| saveDir | Directory to save the plots |
| testD, testL | Optional. The matrix of (independent) test expression data, and the corresponding vector of labels. testL must be named according to the row names of testD. |
| pos | Number of genes to discard. Interpreted the same way as in compact.tree and preds.at |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| doAddEigengene | If TRUE, the eigengene of each module will be added to the corresponding heatmap. |
| scalePngs | If not 1, the size of pngs will be adjusted using this parameter. A typical value would be 7. |
| ... | Additional arguments. Passed to pheatmap.type |

Value

A list of:

| | |
|---------|---|
| call | The call that created the results |
| saveDir | An echo of the input argument determining where the plots are saved |

Examples

```
## Data:
data(aml)
data(mds)
data(pigengene)
d1 <- rbind(aml,mds)

## Plotting the heatmaps of all modules:
module.heatmap(pigengene=pigengene, saveDir="heatmaps", pos=0, verbose=1)

## Fiting the trees:
trees <- make.decision.tree(pigengene=pigengene, Data=d1,
  saveDir="trees", minPerLeaf=14:15, doHeat=FALSE,verbose=3,
  toCompact=15)

## Plotting the heatmaps of only the modules in the tree:
module.heatmap(c5Tree=trees$c5Trees[["15"]], pigengene=pigengene,
  saveDir="treeHeatmaps", pos=0, verbose=1)
```

| | |
|--------------------|---|
| one.step.pigengene | <i>Runs the entire Pigengene pipeline</i> |
|--------------------|---|

Description

Runs the entire Pigengene pipeline, from gene expression to compact decision trees in a single function. It identifies the gene modules using coexpression network analysis, computes eigengenes, learns a Bayesian network, fits decision trees, and compact them.

Usage

```
one.step.pigengene(Data, saveDir="Pigengene", Labels, testD=NULL,
  testLabels=NULL, doBalance=TRUE, RsquaredCut=0.8, costRatio=1,
  toCompact=FALSE, bnNum=0, bnArgs=NULL, useMod0=FALSE, mit="All",
  verbose=0, doHeat=TRUE, seed=NULL, dOrderByW=TRUE, naTolerance=0.05,
  doNetOnly=FALSE, idType="ENTREZID", pathwayDb=NULL, OrgDb=org.Hs.eg.db)
```

Arguments

| | |
|-------------|---|
| Data | A matrix or data frame (or list of matrices or data frames) containing the training expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. For example, from RNA-Seq data, $\log(\text{RPKM}+1)$ can be used. |
| Labels | A (preferably named) vector containing the Labels (condition types) for the training Data. Or, if Data is a list, a list of label vectors corresponding to the data sets in Data. Names must agree with rows of Data. |
| saveDir | Directory to save the results. |
| testD | Test expression data with syntax similar to Data, possibly with different rows and columns. This argument is optional and can be set to NULL if test data are not available. |
| testLabels | A (preferably named) vector containing the Labels (condition types) for the test Data. This argument is optional and can be set to NULL if test data are not available. |
| doBalance | Boolean. Whether the data should be oversampled before identifying the modules so that each condition contribute roughly the same number of samples to clustering. |
| RsquaredCut | A threshold in the range [0,1] used to estimate the power. A higher value can increase power. For technical use only. See pickSoftThreshold for more details. A larger value generally leads to more modules. |
| costRatio | A numeric value, the relative cost of misclassifying a sample from the first condition vs. misclassifying a sample from the second condition. |
| toCompact | An integer value determining which decision tree to shrink. It is the minimum number of genes per leaf imposed when fitting the tree. Set to FALSE to skip compacting, to NULL to automatically select the maximum value. |
| bnNum | Desired number of bootstrapped Bayesian networks. Set to 0 to skip BN learning. |
| bnArgs | A list of arguments passed to learn.bn function. |
| useMod0 | Boolean, whether to allow module zero (the set of outliers) to be used as a predictor in the decision tree(s). |
| mit | The "module identification type", a character vector determining the reference conditions for clustering. If 'All' (default), clustering is performed using the entire data regardless of condition. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| doHeat | If TRUE the heatmap of expression of genes in the modules that contribute to the tree will be plotted. |
| seed | Random seed to ensure reproducibility. |
| dOrderByW | If TRUE, the genes will be ordered in the csv file based on their absolute weight in the corresponding module. |
| naTolerance | Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input . |

| | |
|-----------|--|
| doNetOnly | If TRUE, the pipeline does not continue after making the network and identifying the modules, e.g., eigengenes will not be computed. |
| idType | A string describing the type of input gene ID e.g., "ENTREZID", "REFSEQ", "SYMBOL". |
| pathwayDb | A character vector determining which enrichment database to be used by the get.enriched.pw function e.g., "GO", "KEGG", "REACTOME", or "NCG". Set to NULL to skip the pathway enrichment analysis. |
| OrgDb | The reference data base to be used. Use e.g. org.Ce.eg.db for 'Celegans' when analysing Celegans data. If OrgDb is not NULL, Org must be NULL. |

Details

This is the main function of the package Pigengene and performs several steps: First, modules are identified in the training expression data, according to mit argument i.e. based on coexpression behaviour in the corresponding conditions. Set it to "All" to use all training data for this step regardless of the condition. Then, if a list of data frames is provided in Data, similarity networks on the data sets are computed and combined into one similarity network for the union of nodes across data sets. Then, the eigengenes for each module and each sample are calculated, where the expression of an eigengene of a module in a sample is the weighted average of the expression of the genes in that module in the sample. Technically, an eigengene is the first principal component of the gene expression in a module. PCA ensures that the maximum variance across all the training samples is explained by the eigengene. Next, (optionally –if bnNum is set to a value greater than 0), several bootstrapped Bayesian networks are learned and combined into a consensus network, in order to detect and illustrate the probabilistic dependencies between the eigengenes and the disease subtype. Next, decision tree(s) are built that use the module eigengenes, or a subset of them, to distinguish the classes (Labels). The accuracy of trees is assessed on the train and (if provided) test data. Finally, the number of required genes for the calculation of the relevant eigengenes is reduced (the tree is 'compacted'). The accuracy of the tree is reassessed after removal of each gene. Along the way, several self explanatory directories, heatmaps and plots are created and stored under saveDir.

Value

A list with the following components:

| | |
|-----------|--|
| call | The call that created the results. |
| modules | A named vector. Names are genes IDs and values are the corresponding module number. |
| wgRes | A list. The results of WGCNA clustering of the Data by wgcn.a.one.step if Data is one matrix. |
| betaRes | A list. The automatically selected beta (power) parameter which was used for the WGCNA clustering. It is the result of the call to <code>calculate.beta</code> using the expression data of mit conditions(s). |
| pigengene | The pigengene object computed for the clusters, result of <code>compute.pigengene</code> . |
| learnrtBn | A list. The results of learn.bn call for learning a Bayesian network using the eigengenes. |

| | |
|------------------|---|
| selectedFeatures | A vector of the names of module eigengenes that were considered during the construction of decision trees. If bnNum >0, this corresponds to the immediate neighbors of the Disease or Effect variable in the consensus network. |
| c5treeRes | A list. The results of <code>make.decision.tree</code> call for learning decision trees that use the eigengenes as features. |

Note

The individual functions are exported to facilitated running the pipeline step-by-step in a customized way.

Examples

```
library(org.Hs.eg.db)
data(aml)
data(mds)
d1 <- rbind(aml,mds)
Labels <- c(rep("AML",nrow(aml)),rep("MDS",nrow(mds)))
names(Labels) <- rownames(d1)
p1 <- one.step.pigengene(Data=d1,saveDir=".", bnNum=10, verbose=1, seed=1,
  Labels=Labels, toCompact=FALSE, doHeat=FALSE)
plot(p1$c5treeRes$c5Trees[["34"]])
```

pheatmap.type

Plots heatmap with clustering only within types.

Description

This function first performs hierarchical clustering on samples (rows of data) within each condition. Then, plots a heatmap without further clustering of rows.

Usage

```
pheatmap.type(Data, annRow, type = colnames(annRow)[1],
doTranspose=FALSE, conditions="Auto",...)
```

Arguments

| | |
|-------------|---|
| Data | A matrix with samples on rows and features (genes) on columns. |
| annRow | A data frame with 1 column or more. Row names must be the same as row names of Data. |
| type | The column of annRow used for determining the condition |
| doTranspose | If TRUE, the matrix will be transposed for the final plot. E.g., if the genes are on the columns of Data, they will be shown on rows of the heatmap. |
| conditions | A character vector that determines the conditions, and their order, to be included in the heatmap. By default ("Auto"), an alphabetical order of all available conditions in annRow will be used. |
| ... | Additional arguments passed to pheatmap function. |

Value

A list of:

| | |
|-----------|---|
| pheatmapS | The results of pheatmap function for each condition |
| pheat | The output of final pheatmap function applied on all data |
| ordering | The ordering of the rows in the final heatmap |
| annRowAll | The row annotation used in the final heatmap |

Note

If type is not determined, by default the first column of annRow is used.

```

pigengene

An object of class Pigengene

Description

This is a toy example object of class `pigengene-class`. It is used in examples of `Pigengene-package`. Gene expression profile of 202 acute myeloid leukemia (AML) cases from Mills et al. study. The profile was compared with the profile of 164 myelodysplastic syndromes (MDS) cases and only the 1000 most differentially expressed genes are included.

Usage

```
data("aml")
```

Format

An object of `pigengene-class`.

Details

The object is made using `compute.pigengene` function from `aml` and `mds` data as shown in the examples. The R CMD build `--resave-data` trick was used to reduce the size of saved object from 3.1 MB to 1.4 MB.

Value

It is an object of `pigengene-class`.

Labels <- c(rep("AML",nrow(aml)),rep("MDS",nrow(mds)))
names(Labels) <- rownames(d1)
modules33 <- eigengenes33$modules[colnames(d1)]
## Computing:
computed <- compute.pigengene(Data=d1, Labels=Labels, modules=modules33,
  saveFile="pigengene.RData", doPlot=FALSE, verbose=3)
class(computed)
plot(computed, fontsize=12, main="Reproduced")
```

pigengene-class

The pigengene class

Description

A pigengene object holds the eigengenes, weights (memberships) and other related information.

Details

A object of class pigengene is the output of `compute.pigengene` function. It is a list containing at least the following components:

- `call` The call that created the results.
- `Reptimes` A named vector reporting the number of repeats for each condition in the oversampling process, which is done by the `balance` function.
- `eigenResults` The full output of `moduleEigengenes` function with some fixes, e.g., we change eigengenes to a matrix, and use genes as its row names. Also, `varExplained` is named according to modules.
- `Data` The data matrix of gene expression.
- `Labels` A character vector giving the condition (type) for each sample (row of Data).
- `eigengenes` The matrix of eigengenes ordered based on `selectedModules` if provided. Rows correspond to samples.
- `membership` The matrix of weights of genes (rows) in all modules (columns).
- `orderedModules` The module assignment numeric vector named with genes and ordered based on module number.
- `annotation` A data frame containing labeling information useful in plotting. It has a column named "Condition". Rows have sample names.

- `saveFile` The file where the pigengene object is saved.
- `weightsCsvFile` The file containing the weights in csv format. See `dOrderByW=TRUE`.
- `weights` The weight matrix, which is also saved in csv format. It has more columns than membership but rows may be in a different order if `dOrderByW=TRUE`.
- `heavyToLow` If `dOrderByW=TRUE`, this will be the ordering of genes according to the modules the belong to, where the genes in each module are ordered based on the absolute value of the weights in that module. Also, the genes in the csv file are in this order.

For 2 or more groups (conditions), additional (optional) components include:

- `pvalues` A numeric matrix with columns "pValue", "FDR", and "Bonferroni". Rows correspond to modules. The null hypothesis is that the eigengene is expressed with the same distribution in all groups (conditions).
- `log.pvalues` A data frame with 1 column containing the logarithm of Bonferroni-adjusted pvalues in base 10.

| | |
|----------------|---|
| plot.pigengene | <i>Plots and saves a pigengene object</i> |
|----------------|---|

Description

Plots a couple of heatmaps of expression of the eigengenes, weights (memberships), and so on. Saves the plots in png format.

Usage

```
## S3 method for class 'pigengene'
plot(x, saveDir = NULL,
     DiseaseColors="Auto",
     fontsize = 35, doShowColnames = TRUE, fontsizeCol = 25,
     doClusterCols = ncol(pigengene$eigengenes) > 1,
     verbose = 2, doShowRownames = "Auto",
     pngfactor = max(2, ncol(pigengene$eigengenes)/16), doMem = FALSE, ...)
```

Arguments

| | |
|-----------------------------|--|
| <code>x</code> | The object from pigengene-class computed by compute.pigengene . |
| <code>saveDir</code> | The directory for saving the plots |
| <code>DiseaseColors</code> | A vector of characters determining color for each disease. Names should match the values in the first column of <code>x\$annotation</code> . |
| <code>fontsize</code> | Passd to pheatmap.type |
| <code>doShowColnames</code> | Boolean |

| | |
|----------------|---|
| fontsizeCol | Numeric |
| doClusterCols | Boolean |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| doShowRownames | Boolean |
| pngfactor | A numeric adjusting the size of the png files |
| do0Mem | If TRUE, module 0 genes are included in the membership heatmap. |
| ... | Passd to pheatmap.type function |

Details

Many of the arguments are passed to [pheatmap](#).

Value

A list of:

| | |
|-------------|---|
| heat | The full output of pheatmap functionion |
| heatNotRows | The full output of pheatmap.type function |

preds.at

Prediction using a possibly compacted tree

Description

A decision tree in Pigengene uses module eigengenes to build a classifier that distinguishes two or more classes. Each eigengene is a weighted average of the expression of all genes in the module, where the weight of each gene corresponds to its membership in the module. Each module might contain dozens to hundreds of genes, and hence the final classifier might depend on the expression of a large number of genes. In practice, it can be desirable to reduce the number of necessary genes used by a decision tree. This function is helpful in observing changes to the classification output after removing genes with lower weights membership. It determines how a given decision tree would classify the expression data after removing a certain number of genes from consideration.

Usage

```
preds.at(c5Tree, pigengene, pos=0, Data)
```

Arguments

| | |
|-----------|--|
| c5Tree | A decision tree that uses eigengenes from the pigengene object to classify the samples from the expression data. |
| pigengene | A object of pigengene-class , output of compute.pigengene |
| pos | Number of genes to be removed from the consideration. Genes are removed in ascending order of their absolute weight in the relevant modules. If 0 (default), the prediction will be done without compacting. |
| Data | The expression possibly new data used for classification |

Value

A list with following components:

| | |
|-------------|--|
| predictions | The vector of predictions after neglecting pos number of genes |
| eigengenes | The values for the eigengenes after neglecting pos number of genes |

See Also

data(pigengene)
d1 <- rbind(aml,mds)

## Fiting the trees:
trees <- make.decision.tree(pigengene=pigengene, Data=d1,
  saveDir="trees", minPerLeaf=15, doHeat=FALSE,verbose=3,
  toCompact=FALSE)
preds1 <- preds.at(c5Tree=trees$c5Trees[["15"]], pigengene=pigengene,
  pos=0, Data=d1)
```

project.eigen

Infers eigengenes for given expression data

Description

This function projects (new) expression data onto the eigengenes of modules from another dataset. It is useful for comparing the expression behaviour of modules accross (biologically related yet independent) datasets, for evaluating the performance of a classifier on new datasets, and for examining the robustness of a pattern with regards to missing genes.

Usage

```
project.eigen(Data, saveFile = NULL, pigengene, naTolerance = 0.05,
  verbose = 0, ignoreModules = c())
```

Arguments

| | |
|---------------|---|
| Data | A matrix or data frame of expression data to be projected. Genes correspond to columns, and rows correspond to samples. Rows and columns must be named. It is OK to miss a few genes originally used to compute the eigengenes, thereby, projection is robust to choose of platform. |
| saveFile | If not NULL, where to save the results in .RData format. |
| pigengene | An object of pigengene-class , usually created by compute.pigengene |
| naTolerance | Upper threshold on the fraction of entries per gene that can be missing. Genes with a larger fraction of missing entries are ignored. For genes with smaller fraction of NA entries, the missing values are imputed from their average expression in the other samples. See check.pigengene.input . |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| ignoreModules | A vector of integers. In order to speed up the projection, it may be desirable to focus only on the eigengenes of a few interesting modules. In that case, the remaining modules can be listed here and will be ignored during projection (Optional). |

Details

For each module, from the pigengene object, the weight (membership) of each gene is retrieved. The eigengene is computed (inferred) on the new data as a linear combination using the corresponding weights. The inferred eigengene vector will be normalized so that it has the same Euclidean norm as the original eigengene vector.

Value

A list of:

| | |
|-------------|---|
| projected | The matrix of inferred (projected) eigengenes |
| replacedNaN | The number of NA entries in the input Data that were replaced with the the average expression of the corresponding gene |
| tooNaGenes | A character vector of genes that were ignored because they had too many NAs |
| notMatched | A character vector of genes in the original eigengene that could not be matched in the given input Data |

Note

The new data should use the same type of biolocal identifiers (e.g. Gene Symbols or ENTREZIDs) as the original data for which the pigengene was constructed. It is, however, not required that the new data originate from the same type of technology, e.g. the eigengenes can be based on microarray experiments, whereas the new data comes from an RNA-Seq experiment. Nor is it necessary that the new dataset contains measurements for all of the genes from the original modules.

See Also

[Pigengene-package](#), [compute.pigengene](#) [moduleEigengenes](#)

Examples

```
## Data:
data(aml)
data(mds)
data(eigengenes33)
d1 <- rbind(aml,mds)
Labels <- c(rep("AML",nrow(aml)),rep("MDS",nrow(mds)))
names(Labels) <- rownames(d1)
toyModules <- eigengenes33$modules[colnames(d1)]
## Computing:
p1 <- compute.pigengene(Data=d1, Labels=Labels, modules=toyModules,
  saveFile="pigengene.RData", doPlot=TRUE, verbose=3)
## How robust projecting is?
p2 <- project.eigen(Data=d1, pigengene = p1, verbose = 1)
plot(p1$eigengenes[, "ME1"], p2$projected[, "ME1"])
cor(p1$eigengenes[, "ME1"], p2$projected[, "ME1"])
```

| | |
|----------------|---|
| pvalues.manova | <i>Computes pvalues for multi-class differential expression</i> |
|----------------|---|

Description

Passes the arguments to [manova](#), which performs multi-class analysis of variance.

Usage

```
pvalues.manova(Data, Labels)
```

Arguments

| | |
|--------|---|
| Data | A matrix or data frame containing the (expression) data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| Labels | A (preferably named) vector containing the Labels (condition types). Names must agree with rows of Data |

Value

A list with following elements:

| | |
|-----------|---|
| call | The call that created the results |
| pvals | The matrix of pvalues with columns "pValue", "FDR", "Bonferroni". Rows are named according to genes, the columns of Data. |
| manovaFit | The full output of manova function. |

Note

[oneway.test](#) function is a better generalizatoion to Welch's t-tst from 2-calsses to multi-class because it dose not assume that the variaces are necessarily equal. However, in practice, with "enough number of samples", the two approaches will lead to similar p-values.

names(Labels) <- rownames(d1)
ps <- pvalues.manova(Data=d1, Labels=Labels)
plot(log10(ps$pvals[, "Bonferroni"])
```

save.if

Saves an object verbosely.

Description

Saves an R object, and reports the size of the saved object in memory and on file.

Usage

```
save.if(x1, file, verbose = 1)
```

Arguments

| | |
|---------|--|
| x1 | The object to be saved. |
| file | Where to save. If NULL, nothing will be saved. |
| verbose | A numeric determining how much detail will be printed. |

Value

A list including file, and a vector of sizes of the object in memory and on file.

| | |
|----------------|------------------------------|
| wgcna.one.step | <i>Module identification</i> |
|----------------|------------------------------|

Description

This function is a wrapper function for WGCNA::blockwiseModules and passes its arguments to it. Some other arguments are fixed.

Usage

```
wgcna.one.step(Data, power, saveDir=".", blockSize = "All", saveTOMs = FALSE,
  doThreads=FALSE, verbose = 0, seed = NULL)
```

Arguments

| | |
|-----------|---|
| Data | A matrix or data frame containing the expression data, with genes corresponding to columns and rows corresponding to samples. Rows and columns must be named. |
| power | Soft-thresholding power for network construction |
| saveDir | The directory to save the results and plots. NULL will disable saving. |
| blockSize | The size of block when the data is too big. If not "All" (default) may introduce artifacts. |
| saveTOMs | Boolean determining if the TOM data should be saved, which can be hundreds of MBs and useful for identifying hubs. |
| doThreads | Boolean. Allows WGCNA to run a little faster using multi-threading but might not work on all systems. |
| verbose | The integer level of verbosity. 0 means silent and higher values produce more details of computation. |
| seed | Random seed to ensure reproducibility. |

Details

Data, power, blockSize, saveTOMs, verbose, and seed are passed to WGCNA::blockwiseModules.

Value

A list with following components

| | |
|--------------|--|
| call | The command that created the results |
| genes | The names of Data columns |
| modules | A numeric vector, named by genes, that reports the module (clustering) assignments. |
| moduleColors | A character vector, named by genes, that reports the color of each gene according to its module assignment |

| | |
|---------|--|
| net | The full output of blockwiseModules function |
| netFile | The file in which the net object is saved |
| power | An echo of the power argument. |
