Package 'scBubbletree'

March 29, 2023

Type Package

Title Quantitative visual exploration of scRNA-seq data

Version 1.0.0

Description scBubbletree is a quantitative method for visual
exploration of scRNA-seq data. It preserves biologically
meaningful properties of scRNA-seq data, such as local and
global cell distances, as well as the density distribution of
cells across the sample. scBubbletree is scalable and avoids
the overplotting problem, and is able to visualize diverse cell
attributes derived from multiomic single-cell experiments.
Importantly, Importantly, scBubbletree is easy to use and to
integrate with popular approaches for scRNA-seq data analysis.

scBubbletree-package   *The R package scBubbletree*

Description

Method for quantitative visualization of single cell RNA-seq data

Details

This package contains functions for clustering, hierarchical grouping of clusters and visualization of scRNA-seq data.

d_500 *Dataset: 500 PBMCs*

Description

d_500 is a list with 3 elements:

1. A = numeric matrix A^500x15 with n=500 rows for PBMCs and f=15 principal components.

2. f = character vector f of length 500. Each element in f represents the predicted cell type of a specific cell.

3. fs = numeric matrix containing normalized gene expressions of 12 marker genes in 500 cells.

Usage

```
data("d_500", package = "scBubbletree")
```

Format

Format of d_500: list

Details

This data is a sample drawn from a larger dataset of 2,700 PBMCs. The original dataset was processed as described in vignette (accessed 23, Sep, 2022):

https://satijalab.org/seurat/articles/multimodal_reference_mapping.html

See R script inst/script/get_d_500.R to see how this dataset was created.

Source

https://satijalab.org/seurat/articles/multimodal_reference_mapping.html

Examples

```
data("d_500", package = "scBubbletree")

A <- d_500$A
base::dim(A)

f <- d_500$f
base::table(f)

fs <- d_500$fs
base::dim(fs)
```

---

d_ccl   *Dataset: scRNA-seq data of 3,918 cells from 5 adenocarcinoma cell*
                                         lines

Description

d_ccl is a list with 3 elements:

1. A = numeric matrix with n=3,918 rows for cells and f=15 principal components

2. m = data.frame meta data

3. e = numeric matrix containing normalized gene expressions of 5 marker genes

Usage

```
data("d_ccl", package = "scBubbletree")
```

Format

Format of d_ccl: list

Details

d_ccl is a scRNA-seq dataset containing a mixture of 3,918 cells from five human lung adenocarci-
noma cell lines (HCC827, H1975, A549, H838 and H2228). The dataset is available here:

https://github.com/LuyiTian/sc_mixology/blob/master/data/ sincell_with_class_5cl.RData

The library has been prepared with 10x Chromium platform and sequenced with Illumina NextSeq
500 platform. Raw data has been processed with Cellranger. The tool demuxlet has been used to
predict the identity of each cell based on known genetic differences between the different cell lines.

See R script inst/script/get_d_ccl.R to see how this dataset was created.

get_bubbletree_dummy | *Build bubbletree given matrix A and vector cs of externally generated cluster IDs*

Description

get_bubbletree_dummy takes two main inputs:

1. numeric matrix $A^{n \times f}$, which represents a low-dimensional projection (obtained e.g. by PCA) of the original high-dimensional scRNA-seq data, with n rows as cells and f columns as low-dimension features.

2. vector cs of cluster IDs of each cell

The function get_bubbletree_dummy performs one main operation. It organizes the bubbles (defined by cs) in a hierarchical dendrogram (bubbletree) which represents the hierarchical relationships between the clusters (bubbles).

Usage

```
get_bubbletree_dummy(x,
                     cs,
                     B = 100,
                     N_eff = 100,
                     cores = 1,
                     round_digits = 2,
                     show_simple_count = FALSE,
                     verbose = TRUE)
```

Arguments

x	numeric matrix ($A^{n \times f}$ with n cells, and f low-dimensional projections of the original single cell RNA-seq dataset)
cs	vector, cluster IDs
B	integer, number of bootstrap iterations to perform in order to generate bubbletree
N_eff	integer, number of cells to draw randomly from each cluster when computing inter-cluster distances. Maximum available number of cells are used for clusters that contain lower number of cells than N_eff
cores	integer, number of PC cores for parallel execution
round_digits	integer, number of decimal places to keep when showing the relative frequency of cells in each bubble

show_simple_count

> logical, if show_simple_count=T, cell counts in each bubble will be divided by 1,000 to improve readability. This is only useful for samples that are composed of millions of cells.

verbose   logical, progress messages

Details

This function is similar to get_bubbletree_kmeans and get_bubbletree_graph. It skips the clustering step. See documentation of get_bubbletree_kmeans and get_bubbletree_graph.

Value

A	input x matrix
k	number of clusters
km	NULL
ph	boot_ph: bootstrap dendrograms H_b; main_ph: consensus dendrogram $\hat{H}$
pair_dist	inter-cluster distances used to generate the dendrograms
cluster	cluster assignments of each cell
input_par	list of all input parameters
tree	ggtree bubbletree object
tree_meta	meta-data associated with the bubbletree

get_bubbletree_graph   *Louvain clustering and hierarchical grouping of k' clusters (bubbles)*

Description

get_bubbletree_graph takes two main inputs:

1. numeric matrix $A^{n \times f}$, which represents a low-dimensional projection (obtained e.g. by PCA) of the original high-dimensional scRNA-seq data, with n rows as cells and f columns as low-dimension features.

2. clustering resolution r

The function get_bubbletree_graph performs two main operations. First, it performs Louvain clustering to identify groups (bubbles) of transcriptionally similar cells; second, it organizes the bubbles in a hierarchical dendrogram (bubbletree) which adequatly represents inter-cluster relationships.

Usage

```
get_bubbletree_graph(x,
                     r,
                     B = 100,
                     N_eff = 200,
                     n_start = 20,
                     iter_max = 100,
                     algorithm = "original",
                     knn_k = 50,
                     cores = 1,
                     round_digits = 2,
                     show_simple_count = FALSE,
                     verbose = TRUE)
```

Arguments

x	numeric matrix ($A^{n \times f}$ with n cells, and f low-dimensional projections of the original single cell RNA-seq dataset)
r	number, clustering resolution
B	integer, number of bootstrap iterations to perform in order to generate bubbletree
N_eff	integer, number of cells to draw randomly from each cluster when computing inter-cluster distances. Maximum available number of cells are used for clusters that contain lower number of cells than N_eff
n_start, iter_max	
	parameters for Louvain clustering, see documentation of function FindClusters, R-package Seurat
algorithm	character, four clustering algorithms: 'original', 'LMR', 'SLM' and 'Leiden', see documentation of function FindClusters, R-package Seurat
knn_k	integer, defines k for the k-nearest neighbor algorithm, see documentation of function FindClusters, R-package Seurat

cores	integer, number of PC cores for parallel execution
round_digits	integer, number of decimal places to keep when showing the relative frequency of cells in each bubble
show_simple_count	
	logical, if show_simple_count=T, cell counts in each bubble will be divided by 1,000 to improve readability. This is only useful for samples that are composed of millions of cells.
verbose	logical, progress messages

Details

For Louvain clustering get_bubbletree_graph uses the function FindClusters implemented in R-package Seurat. For additional information on the clustering procedure see the documentation of FindClusters. To organize the resulting clusters in a hierarchical dendrogram the algorithm performs the following steps:

1. In bootrap iteration b from $1 : B$

2. draw up to N_{eff} number of cells at random from each cluster without replacement

3. compute Euclidean distances (in space $A^{n \times f}$) between all pairs of cells in cluster i and cluster j

4. compute mean Euclidean distance between cluster i and j and populate inter-cluster distance matrix $D_b^{k \times k}$

5. perform hierarchical clustering with average linkage based on $D_b^{k \times k}$ to generate dendrogram H_b

6. compute average distance matrix $\hat{D}$ and use is as input to build consensus hierarchical dendrogram ($\hat{H}$; bubbletree) with average linkage

7. quantify branch robustness in $\hat{H}$ count how many times each branch is found among bootrap dendrograms (H_b

8. visualize the bubbletree ($\hat{H}$) with R-package ggtree

Value

A	input x matrix
k	number of clusters
r	clustering resolution
ph	boot_ph: bootstrap dendrograms H_b; main_ph: consensus dendrogram $\hat{H}$
pair_dist	inter-cluster distances used to generate the dendrograms
cluster	cluster assignments of each cell
input_par	list of all input parameters
tree	ggtree bubbletree object
tree_meta	meta-data associated with the bubbletree

get_bubbletree_kmeans   *k-means clustering and hierarchical grouping of k clusters (bubbles)*

Description

get_bubble_kmeans takes two main inputs:

1. numeric matrix $A^{n \times f}$, which represents a low-dimensional projection (obtained e.g. by PCA) of the original high-dimensional scRNA-seq data, with n rows as cells and f columns as low-dimension features.

2. number k of clusters

The function get_bubble_kmeans performs two main operations. First, it performs k-means clustering to identify groups (bubbles) of transcriptionally similar cells; second, it organizes the bubbles in a hierarchical dendrogram (bubbletree) which adequatly represents inter-cluster relationships.

Usage

```
get_bubbletree_kmeans(x,
                      k,
                      B = 100,
                      N_eff = 200,
                      n_start = 1000,
                      iter_max = 300,
                      kmeans_algorithm = "MacQueen",
```

```
                          cores = 1,
                          round_digits = 2,
                          show_simple_count = FALSE,
                          verbose = TRUE)
```

Arguments

x	numeric matrix ($A^{n \times f}$ with n cells, and f low-dimensional projections of the original single cell RNA-seq dataset)
k	integer, number of clusters
B	integer, number of bootstrap iterations to perform in order to generate bubbletree
N_eff	integer, number of cells to draw randomly from each cluster when computing inter-cluster distances. Maximum available number of cells are used for clusters that contain lower number of cells than N_eff
n_start, iter_max, kmeans_algorithm	
	parameters for k-means clustering, see documentation of function k-means, R-package stats
cores	integer, number of PC cores for parallel execution
round_digits	integer, number of decimal places to keep when showing the relative frequency of cells in each bubble
show_simple_count	
	logical, if show_simple_count=T, cell counts in each bubble will be divided by 1,000 to improve readability. This is only useful for samples that are composed of millions of cells.
verbose	logical, progress messages

Details

For k-means clustering get_bubble_kmeans uses the function kmeans implemented in R-package stats (version 4.2.0). For additional information on the clustering procedure see the documentation of kmeans. To organize the resulting clusters in a hierarchical dendrogram the algorithm performs the following steps:

1. In bootrap iteration b from $1 : B$

2. draw up to N_{eff} number of cells at random from each cluster without replacement

3. compute Euclidean distances (in space $A^{n \times f}$) between all pairs of cells in cluster i and cluster j

4. compute mean Euclidean distance between cluster i and j and populate inter-cluster distance matrix $D_b^{k \times k}$

5. perform hierarchical clustering with average linkage based on $D_b^{k \times k}$ to generate dendrogram H_b

6. compute average distance matrix $\hat{D}$ and use is as input to build consensus hierarchical dendrogram ($\hat{H}$; bubbletree) with average linkage

7. quantify branch robustness in $\hat{H}$ count how many times each branch is found among bootrap dendrograms (H_b

8. visualize the bubbletree ($\hat{H}$) with R-package ggtree

Value

A	input matrix x
k	number of clusters
km	k-means clustering results identical to those generated by function k-means from R-package stats
ph	boot_ph: bootstrap dendrograms H_b; main_ph: consensus dendrogram $\hat{H}$
pair_dist	inter-cluster distances used to generate the dendrograms
cluster	cluster assignments of each cell
input_par	list of all input parameters
tree	ggtree bubbletree object
tree_meta	meta-data associated with the bubbletree

get_cat_tiles	*Visualization of categorical cell features using tile plots*

Description

get_cat_tiles creates tile plot to visualize the relative frequency of categorical cell features between and within the bubbles of a bubbletree

Usage

```
get_cat_tiles(btd,
              f,
              integrate_vertical,
              round_digits = 2,
              tile_text_size = 3,
              tile_bw = FALSE,
              x_axis_name = "Feature",
              rotate_x_axis_labels = TRUE)
```

Arguments

`btd`	bubbletree object
`f`	character vector, categorical cell features
`integrate_vertical`	
	logical, if integrate_vertical=TRUE: relative frequency of the features is shown in each bubble, if integrate_vertical=FALSE: relative frequencies of the features is shown within each bubble
`round_digits`	integer, number of decimal places to keep when showing the relative frequency of cells in each bubble
`tile_text_size`	integer, size of tile labels
`x_axis_name`	character, x-axis title
`rotate_x_axis_labels`	
	logical, should the x-axis labels be shown horizontally (rotate_x_axis_labels = FALSE) or vertically (rotate_x_axis_labels = TRUE)
`tile_bw`	logical, tile grayscale (tile_bw = TRUE) vs. color (tile_bw = FALSE, default)

Details

get_cat_tiles uses two main inputs:

1. bubbletree object

2. character vector of categorical cell features.

The order of the cells used to generat the bubbletree (input 1.) should correspond to the order of cells in the vector of categorical cell features (input 2.)

This function computes:

1. with integrate_vertical=T: relative frequencies of each feature across the different bubbles

2. with integrate_vertical=F: within-bubble relative frequencies (composition) of different features

Value

`plot`	ggplot2, tile plot
`table`	data.frame, raw data used to generate the plot

Author(s)

Simo Kitanovski <simo.kitanovski@uni-due.de>

get_gini	*Gini impurity index computed for a clustering solution and a vector of categorical cell feature labels*

Description

How well is a set of categorical feature labels (e.g. cell type predictions) partitioned accross the different clusters of a clustering solution? We can assess this using the Gini impurity index (see details below).

Inputs are two equal-sized vectors:

1) clusters IDs

2) labels

Output:

1) cluster-specific purity -> Gini impurity (GI) index

2) clustering solution impurity -> Weighted Gini impurity (WGI) index

Usage

```
get_gini(labels, clusters)
```

Arguments

labels   character or numeric vector of labels

clusters   character or numeric vector of cluster IDs

Details

To quantify the purity of a cluster (or bubble) i with n_i number of cells, each of which carries one of L possible labels (e.g. cell type), we computed the Gini impurity index:

$GI_i = \sum_{j=1}^{L} \pi_{ij}(1 - \pi_{ij})$,

with π_{ij} as the relative frequency of label j in cluster i. In homogeneous ('pure') clusters most cells carry a distinct label. Hence, the π's are close to either 1 or 0, and GI takes on a small value close to zero. In 'impure' clusters cells carry a mixture of different labels. In this case most π are far from either 1 or 0, and GI diverges from 0 and approaches 1. If the relative frequencies of the different labels in cluster i are equal to the (background) relative frequencies of the labels in the sample, then cluster i is completely 'impure'.

To compute the overall Gini impurity of a bubbletree, which represents a clustering solution with k bubbles, we estimated the weighted Gini impurity (WGI) by computing the weighted (by the cluster size) average of the GIs:

$WGI = \sum_{i=1}^{k} GI_i n_i / n$,

with n_i as the number of cells in cluster i and $n = \sum_i n_i$.

Value

gi   Gini impurity of each bubble

wgi   Weighted Gini impurity index of the bubbletree

Author(s)

Simo Kitanovski <simo.kitanovski@uni-due.de>

get_gini_k   *Gini impurity index computed for a list of clustering solutions obtained
                               by functions get_k or get_r and a vector of categorical cell feature
                               labels*

Description

Given The Gini impurity (GI) index allows us to quantitatively evaluate how well a set of labels (categorical features) are split across a set of bubbles. We have a completely perfect split (GI = 0) when each bubble is 'pure', i.e. each bubble contains labels coming from distinct a class. In contrast to this, we have completely imperfect split (GI = 1) when the relative frequency distribution of the labels in each bubble is identical to the background relative frequency distribution of the labels.

Cell type predictions are a type of categorical features that are often used to evaluate the goodness of the clustering. get_gini_k takes as input: 1) a vector of labels for each cell (e.g. cell types) and 2) object returned by function get_k or get_r. Then it computes for each k or r the cluster purity and weightred gini impurity of each clustering solution mean GI, which is another way of finding an optimal clustering resolution.

Usage

```
get_gini_k(labels, obj)
```

Arguments

labels   character/factor vector of labels

obj   object returned by functions get_k or get_r

Details

To quantify the purity of a cluster (or bubble) i with n_i number of cells, each of which carries one of L possible labels (e.g. cell type), we computed the Gini impurity index:

$GI_i = \sum_{j=1}^{L} \pi_{ij}(1 - \pi_{ij}),$

with π_{ij} as the relative frequency of label j in cluster i. In homogeneous ('pure') clusters most cells carry a distinct label. Hence, the π's are close to either 1 or 0, and GI takes on a small value close to zero. In 'impure' clusters cells carry a mixture of different labels. In this case most π are far from either 1 or 0, and GI diverges from 0 and approaches 1. If the relative frequencies of the different labels in cluster i are equal to the (background) relative frequencies of the labels in the sample, then cluster i is completely 'impure'.

To compute the overall Gini impurity of a bubbletree, which represents a clustering solution with k bubbles, we estimated the weighted Gini impurity (WGI) by computing the weighted (by the cluster size) average of the GIs:

$WGI = \sum_{i=1}^{k} GI_i n_i / n,$

with n_i as the number of cells in cluster i and $n = \sum_i n_i$.

Value

gi_summary   GI for each bubble of a clustering solution with clustering resolution k or r

wgi_summary   WGI for each clustering solution with clustering resolution k or r

get_k   *Finding optimal number k of clusters*

Description

To perform k-means clustering we must specify a number k of clusters. Data-driven metrics, such as the Gap statistic or the within-cluster sum of squares (WCSS), can be used to infer appropriate k from the data. get_k computes the Gap statistic and WCSS for a number of clusters ks.

Usage

```
get_k(x,
      ks,
      B_gap = 20,
      n_start = 1000,
      iter_max = 300,
      kmeans_algorithm = "MacQueen",
      cores = 1,
      verbose = TRUE)
```

Arguments

x	numeric matrix A^{nxf} with n cells, and f low-dimensional projections
ks	integer vector, k values to consider
B_gap	integer, number of Monte Carlo ("bootstrap") samples taken when computing the Gap statistic (see documentation of function clusGap, R-package cluster)
n_start, iter_max, kmeans_algorithm	
	parameters for k-means clustering, see documentation of function k-means, R-package stats
cores	integer, number of PC cores for parallel execution
verbose	logical, progress messages

Details

To compute the Gap statistic get_k adapts the algorithm of function clustGap from R-package cluster (version 2.1.3). For k-means clustering get_k uses the function kmeans implemented in R-package stats (version 4.2.0). For additional information see the respective documentations.

Value

boot_obj	The results: k-means clustering solutions, the Gap statistic and WCSS
gap_stats_summary, wcss_stats_summary	
	main results; Gap statistic and WCSS estimates. Means, standard errors and 95% confidence intervals are provided for each k
gap_stats, wcss_stats	
	intermediate results; Gap statistic and WCSS estimates for each k and bootstrap iteration b

b$gap_stats_summary
```

---

get_num_tiles   *Visualization of numeric cell features using tile plots*

Description

get_num_tiles creates tile plot to visualize a summary (e.g. mean, median or sum) of a numeric cell feature (e.g. gene expression of a specific gene) in each bubble of a bubbletree

Usage

```
get_num_tiles(btd,
              fs,
              summary_function,
              round_digits = 2,
              tile_text_size = 3,
              tile_bw = FALSE,
              x_axis_name = "Feature",
              rotate_x_axis_labels = TRUE)
```

Arguments

btd   bubbletree object

fs   numeric vector or matrix, numeric cell features

summary_function
                 character, "mean", "median" or "sum", "pct nonzero", "pct zero", summaries are allowed

round_digits   integer, number of decimal places to keep when showing the relative frequency of cells in each bubble

tile_text_size   integer, size of tile labels

x_axis_name   character, x-axis title

rotate_x_axis_labels

> logical, should the x-axis labels be shown horizontally (rotate_x_axis_labels = FALSE) or vertically (rotate_x_axis_labels = TRUE)

tile_bw   logical, tile grayscale (tile_bw = TRUE) vs. color (tile_bw = FALSE, default)

Details

get_num_tiles uses two main inputs:

1. bubbletree object

2. numeric vector or matrix of numeric cell features.

The order of the cells used to generat the bubbletree (input 1.) should correspond to the order of cells in the vector/matrix of numeric cell features (input 2.)

This function computes summaries of numeric cell feature in each bubble: 1. mean = mean of feature 2. median = median of feature 3. sum = sum of feature 4. pct nonzero = sum of cells with feature > 0 5. pct zero = sum of cells with feature = 0

Important note: NA and NULL values are omitted.

Value

plot   ggplot2, tile plot

table   data.frame, raw data used to generate the plot

```
# input data
data("d_500", package = "scBubbletree")
A <- d_500$A
fs <- d_500$fs

b <- get_bubbletree_kmeans(x = A,
                    k = 8,
                    N_eff = 100)

g <- get_num_tiles(btd = b,
                    fs = fs,
                    summary_function = "mean",
                    round_digits = 2,
                    tile_text_size = 3,
                    tile_bw = TRUE,
                    x_axis_name = "Gene expression",
```

```
                    rotate_x_axis_labels = TRUE)

    b$tree|g$plot
```

---

get_num_violins   *Visualization of numeric cell features using violin plots*

Description

get_num_violins creates violin plot to visualize the distribution of of numeric cell features (e.g. gene expressions) in each bubble of a bubbletree

Usage

```
get_num_violins(btd,
                fs,
                x_axis_name = "Feature distribution",
                rotate_x_axis_labels = TRUE)
```

Arguments

btd   bubbletree object

fs   numeric vector or matrix, numeric cell features

x_axis_name   character, x-axis title

rotate_x_axis_labels
                       logical, should the x-axis labels be shown horizontally (rotate_x_axis_labels = FALSE) or vertically (rotate_x_axis_labels = TRUE)

Details

get_num_violins uses two main inputs:

1. bubbletree object

2. numeric vector or matrix of numeric cell features.

The order of the cells used to generat the bubbletree (input 1.) should correspond to the order of cells in the vector/matrix of numeric cell features (input 2.)

This function visualizes densities of numeric cell feature in the different bubble.

Value

plot   ggplot2, violin plot

table   data.frame, raw data used to generate the plot

get_r   *Finding optimal clustering resulution r and number of communities k'*

Description

To perform Louvain clustering we must specify a clustering resolution r. Data-driven metrics, such as the Gap statistic or the within-cluster sum of squares (WCSS) can be used to infer appropriate r from the data. get_r computes the Gap statistic and WCSS for a vector of clustering resolutions rs.

Usage

```
get_r(x,
    rs,
    B_gap = 20,
    n_start = 20,
    iter_max = 100,
    algorithm = "original",
    knn_k = 50,
    cores = 1,
    verbose = TRUE)
```

Arguments

x	numeric matrix A^{nxf} with n cells, and f low-dimensional projections
rs	number vector, r values to consider
B_gap	integer, number of Monte Carlo ("bootstrap") samples taken when computing the Gap statistic (see documentation of function clusGap, R-package cluster)
n_start, iter_max	
	parameters for Louvain clustering, see documentation of function FindClusters, R-package Seurat
algorithm	character, four clustering algorithms: 'original', 'LMR', 'SLM' and 'Leiden', see documentation of function FindClusters, R-package Seurat
knn_k	integer, defines k for the k-nearest neighbor algorithm, see documentation of function FindClusters, R-package Seurat
cores	integer, number of PC cores for parallel execution
verbose	logical, progress messages

Details

To compute the Gap statistic get_r adapts the algorithm of function clustGap from R-package cluster (version 2.1.3). For Louvain clustering get_r uses the function FindClusters implemented in R-package Seurat. For additional information see the respective documentations.

Value

boot_obj	The results: k-means clustering solutions, the Gap statistic and WCSS
gap_stats_summary, wcss_stats_summary	
	main results; Gap statistic and WCSS estimates. Means, standard errors and 95% confidence intervals are provided for each r and k'
gap_stats, wcss_stats	
	intermediate results; Gap statistic and WCSS estimates for each r and k' and bootstrap iteration b
